Weapons: the need to replace ageing and deteriorating stock

SIR — Your Editorial on resistance to non-proliferation of nuclear weapons is, in my view, a good example of selective presentation of data (*Nature* **461**, 11; 2009). As first director of the US Defense Threat Reduction Agency, from 1998 to 2001, I consider a few corrections are in order.

Although the predicted lifetimes of the plutonium pits of US weapons are 40–80 years, the thousands of non-nuclear components in the pit's environment are less stable. Radiation damage, loss of plasticizers and binders, and other changes mean that they could eventually compromise the performance of highly optimized cold-war weapons, designed to minimize weight and use of plutonium and uranium.

Replacing these parts with exact equivalents is often not possible because the materials and production processes no longer exist or because their production is precluded by changes in environmental and safety regulations. Confidence in performance and the willingness of politicians to accept expert judgement about it are likely to suffer.

The proposed Reliable Replacement Warhead (RRW) was designed using nuclear systems that were more robust and had higher margins against failure, thus relaxing the stress on new non-nuclear systems intended for replacement and future production. As a bonus, the safety and surety features of the weapon were improved. It is not a stalking horse for nuclear testing but would increase military and congressional confidence in weapons performance; this assurance is vital as falling numbers render each weapon more important for deterrence.

Unlike the unlamented Robust Nuclear Earth Penetrator, which failed tests of both utility and

credibility, the RRW does not represent a lowering of thresholds against nuclear use, nor an opening to worrying policies of pre-emption.

You should not chide the United States for desiring to do what the British, French, Russian and Chinese governments are also doing or planning to do — namely, modernizing their stockpiles with new weapons systems.

Weapons: existing stockpile can be safely maintained

SIR — You are correct to state that the Reliable Replacement Warhead (RRW) programme would do nothing to improve the reliability of the US nuclear arsenal (*Nature* **461**, 11; 2009). It is possible that the “powerful figures within Obama’s own administration” are being advised by people associated with the weapons laboratories who may have an interest in derailing a ratification of the Comprehensive Test Ban Treaty.

Existing nuclear weapons are already very reliable and their safety features are adequate, as a series of reports by R. E. Kidder of Lawrence Livermore National Laboratory affirmed. (For further details, see go.nature.com/yCmG4W.) As US weapons are comfortably tolerant of small variations that may occur in materials or the manufacturing process, they can be remanufactured without explosive proof-testing.

Those in favour of the RRW claim that it would not need nuclear testing. This is because the RRW would be composed of an existing primary stage, which is where many of the uncertainties of nuclear weapons design reside, and probably also an existing secondary stage. However, very few people outside the weapons-design community

would trust deployment of a weapon that has not been tested.

As a result, the pressure to test any RRW could well derail the ratification of the test ban treaty. Failing to ratify this treaty (not to mention resuming nuclear testing) would do great harm to US national interests as well as those of the world at large.

Others argue that the RRW programme is needed to maintain expertise in weapons physics. This can be done without the RRW. There is no need for it or any continued nuclear proof-testing.

Many types of action are required to tackle climate change

SIR — Sanjay Khanna’s survey of climate-campaign activities (*Nature* **461**, 1058–1059; 2009) implies that the arts and advertising ought to be helping to bring into being a “worldwide consensus for action”. But the point is not to engineer a global consensus for action, as though the ‘action’ that is being sought is somehow self-evident, unambiguous and uncontested. Palpably, it is not.

Instead, the urgency is to articulate the many types of action — individual or collective, selfish or altruistic, conservative or radical — that can be justified by the prospect of climate change, and to understand why, in a plural and contradictory world, these actions may differ. And then to accommodate them.

To paraphrase one of the six messages that came out of the Copenhagen climate congress in March, it is not inaction that is inexcusable. What is inexcusable is to pretend that there is just one message, one voice, one number to be communicated, that there is just one action agenda that (the science of) climate change

demands from us, and that the arts and advertising can deliver it.

Decarbonization figures for India and China unconvincing

SIR — In their Opinion articles, Rajendra Pachauri (*Nature* **461**, 1054; 2009) and Jiahua Pan (*Nature* **461**, 1055; 2009) include figures that show business-as-usual perspectives on India’s and China’s emissions growth in coming decades. Both figures indicate that the two countries’ economies have already made the transition to high rates of decarbonization. This would put them in a very strong position in international climate negotiations, but I find the figures unconvincing.

India’s five business-as-usual projections include different assumptions of annual rates of decarbonization, from 1.0% up to 3.3%. Four of these greatly exceed the 1987–2006 average of 1.1%. The single business-as-usual projection for China suggests an annual rate of decarbonization of 6.5% per year to 2030, which is almost three times the 1987–2006 average. China’s emissions grew by 12.2% per year from 2000 to 2007, and under business-as-usual are now expected to grow by only 2.5% per year to 2030.

If India and China have indeed already implemented policies that will decarbonize their economies by 3% per year and more, then it would be very good news indeed, as global rates of about 5% (or more) per year would be necessary to achieve an 80% emissions reduction below 1990 levels by 2050, assuming modest economic growth. But if India and China are overoptimistic about future rates of business-as-usual decarbonization, then the challenge of stabilizing concentrations of carbon
